Advancing a robust portfolio *focused on muscle diseases*

We are building a leading muscle disease company dedicated to advancing innovative life-transforming therapeutics for people living with genetically driven diseases. Our initial focus is on myotonic dystrophy type 1 (DM1), Duchenne muscular dystrophy (DMD) and facioscapulohumeral muscular dystrophy (FSHD).

Our Pipeline

PROGRAM	TARGET	DISCOVERY	PRECLINICAL	PHASE 1	PHASE 2	PHASE 3	ESTIMATED PATIENTS
Myotonic Dystrophy (DM1)	DMPK						US: >40,000 Europe: >74,000
Duchenne Muscular Dystrophy (DMD)	Exon 51 Exon 53 Exon 45 Exon 44						US: ~12,000-15,000 Europe: ~25,000
Facioscapulohumeral Muscular Dystrophy (FSHD)	DUX4						US: ~16,000-38,000 Europe: ~35,000

PIPELINE EXPANSION OPPORTUNITIES

Rare Skeletal, Cardiac, Metabolic

Our Programs

Myotonic Dystrophy Type 1 (DM1)

OVERVIEW

- Mutation in the *DMPK* gene
- Onset at any point, depending on DM1 phenotype
- Life expectancy of 45-60 years

CLINICAL PRESENTATION

- Myotonia
- Muscle weakness
- Cardiac arrhythmia
- Pulmonary abnormalities

POPULATION

- >40,000 (US)
- >74,000 (Europe)

Our DM1 program candidates:

- Consist of a proprietary Fab conjugated with the linker to an antisense oligonucleotide (ASO)
- Are designed to address the genetic basis of DM1 by reducing the levels of mutant *DMPK* RNA in the nucleus, releasing splicing proteins, allowing normal mRNA processing and translation of normal proteins and potentially stopping or reversing disease

Preclinical studies have shown reduction of nuclear foci and correction of splicing in DM1 patient cells, reversal of myotonia after a single dose in a DM1 disease model, robust reduction in toxic human nuclear *DMPK* in a novel *in vivo* model developed by Dyne, durability of response up to 12 weeks and enhanced muscle distribution as evidenced by reduced levels of cytoplasmic wild-type *DMPK* RNA.

Duchenne Muscular Dystrophy (DMD)

OVERVIEW

- Mutation in the *DMD* gene that encodes for dystrophin
- Onset in first few years of life
- Life expectancy ~30 years

CLINICAL PRESENTATION

- Muscle weakness
- Progressive loss of function
- Loss of ambulation
- Respiratory/cardiac failure

POPULATION

- ~12,000 - 15,000 (US)
- ~25,000 (Europe)

Our DMD program candidates:

- Consist of a proprietary Fab conjugated with the linker to a phosphorodiamidate morpholino oligomer (PMO)
- Are designed to deliver a PMO to muscle tissue to promote the skipping of specific *DMD* exons in the nucleus, allowing muscle cells to create a more complete, functional dystrophin protein and potentially stop or reverse disease progression

In *in vitro* and *in vivo* preclinical studies, Dyne's FORCE™ platform has shown increased exon skipping, increased dystrophin expression, reduced muscle damage and increased muscle function.

Our initial development efforts in DMD are focused on developing a therapy for patients with mutations amenable to skipping exon 51. We plan to expand our DMD franchise and develop therapies for patients with mutations amenable to skipping other exons, including exons 53, 45 and 44.

Facioscapulohumeral Muscular Dystrophy (FSHD)

OVERVIEW

- Aberrant expression of *DUX4*
- Onset in teen years or young adulthood
- Normal life expectancy

CLINICAL PRESENTATION

- Progressive wasting and skeletal muscle loss
- Significant physical limitations

POPULATION

- ~16,000 - 38,000 (US)
- ~35,000 (Europe)

Our FSHD program candidates:

- Consist of a proprietary Fab conjugated with the linker to an ASO that is designed to address the genetic basis of FSHD by reducing *DUX4* expression in muscle tissue

We have an agreement with the University of Mons that provides us with exclusive access to intellectual property to target the genetic cause of FSHD and complements our own proprietary platform for precision delivery into muscle cells.

We generated proof-of-concept data showing that the FORCE platform reduced expression of key DUX4 biomarkers in FSHD patient myotubes.
